

Codex seed compression feature map

The full seed is a high-fidelity Codex CLI port. Each smaller seed spends fewer physical lines on the same behavioral surface. Color encodes retained feature depth, not benchmark reward.

FEATURE RETENTION: QUALITATIVE DEPTH FROM SEED-CODE INSPECTION

Reading left to right: early compression removes readability and structure first; later compression removes behavior. The 700-line seed is the first major behavioral break because model compaction is gone. The 400-line seed keeps the Codex prompt and core shell tools but drops plan updates and most metadata. The 100-line endpoint is a minimal baseline, not a Codex port.
